

EXERCISE 4: Database Normalization – Doctor & Patient Appointment

Original Table: SURGERY_SCHEDULE

| Doctor_number | Doctor_name | Patient_number | Patient_name | Appointment Date Time | Surgery_code | Surgery_name |
|---------------|---------------|----------------|---------------|-----------------------|--------------|-----------------|
| D1204 | Sam Evans | P101 | Gil Ramirez | 01-10-2025 10:00 | S22 | Appendicitis |
| D1204 | Sam Evans | P108 | John Smith | 01-10-2025 12:00 | S22 | Appendicitis |
| D5050 | Julia Roberts | P106 | Paul McCall | 01-10-2025 10:00 | S10 | Cholecystectomy |
| D5050 | Julia Roberts | P106 | Paul McCall | 02-10-2025 14:00 | S10 | Cholecystectomy |
| D3553 | Ann Pearson | P108 | John Smith | 02-10-2025 10:00 | S22 | Appendicitis |
| D3553 | Ann Pearson | P110 | Andres Walker | 03-10-2025 18:00 | S13 | Hip Replacement |

STEP 1: First Normal Form (1NF)

1.1.Rule 1NF

- The first normal form (1NF) requires:
 - "Each attribute must contain only a single value".
 - "Each attribute must be atomic (not be a combination of multiple columns)"

1.2.Issue

- The table has repeating data (Doctor, Surgery, Patient repeated many times).
- But no multi-valued attributes — so it's technically in 1NF, but not well-structured (repetition leads to anomalies).

1.3.Solution

- We identify a unique composite key: {Doctor_number, Patient_number, Appointment_Date, Time} – This uniquely identifies each appointment.
- All values are atomic => so the table is now 1NF.

1.4.PK and FKS

The PK for the SURGERY_SCHEDULE table is a unique composite key: {Doctor_number, Patient_number, Appointment_Date, Time}.

1.5.ERDs

| SURGERY_SCHEDULE | |
|------------------|------------------|
| PK | Doctor_number |
| PK | Patient_number |
| PK | Appointment date |
| PK | Time |
| | Time |
| | Doctor_name |
| | Patient_name |
| | Surgery_code |
| | Surgery_name |

1.6.Example data

| PK: Doctor_number | PK: Patient_number | PK: Appointment_Date | PK: Time | Doctor_name | Patient_name | Surgery_code | Surgery_name |
|----------------------|-----------------------|-------------------------|-------------|---------------|---------------|--------------|-----------------|
| D1204 | P101 | 01-10-2025 | 10:00 | Sam Evans | Gil Ramirez | S22 | Appendicitis |
| D1204 | P108 | 01-10-2025 | 12:00 | Sam Evans | John Smith | S22 | Appendicitis |
| D5050 | P106 | 01-10-2025 | 10:00 | Julia Roberts | Paul McCall | S10 | Cholecystectomy |
| D5050 | P106 | 02-10-2025 | 14:00 | Julia Roberts | Paul McCall | S10 | Cholecystectomy |
| D3553 | P108 | 02-10-2025 | 10:00 | Ann Pearson | John Smith | S22 | Appendicitis |
| D3553 | P110 | 03-10-2025 | 18:00 | Ann Pearson | Andres Walker | S13 | Hip Replacement |

1.7.Reflections

- Table is in 1NF because:
 - No repeating groups.
 - All fields atomic.
- But still redundant – e.g., Sam Evans repeated multiple times for D1204 => violates 2NF.

STEP 2: Second Normal Form (2NF)

2.1 Rule (2NF)

- Must be in 1NF.
- All non-key attributes must depend on the whole primary key (**no partial dependency**).

2.2 Issue

- In 1NF table:
 - Doctor_name depends only on Doctor_number.
 - Patient_name depends only on Patient_number.
 - Surgery_name depends only on Surgery_code.
- These are partial dependencies, so the table is not in 2NF.

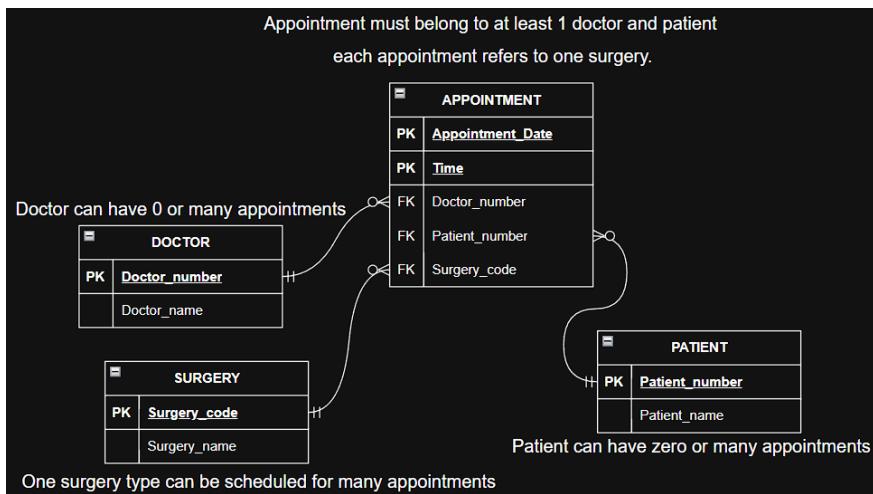

2.3 Solution

- Split the table into separate entities
 1. DOCTOR (Doctor info)
 2. PATIENT (Patient info)
 3. SURGERY (Surgery info)
 4. APPOINTMENT (Linking Doctor, Patient, Surgery and Date/Time)

2.4 PK and FKs

- The primary key for DOCTOR table is the Doctor_number.
- The primary key for PATIENT table is the Patient_number.
- The primary key for SURGERY table is the Surgery_code.
- The primary key for APPOINTMENT table is the Appointment_Date and Time.
- Doctor_number, Patient_number, Surgery_code are FKs in APPOINTMENT table.

2.5 ERDs

2.6 Sample data

| DOCTOR | |
|----------------------|---------------|
| PK: Doctor_number | Doctor_name |
| D1204 | Sam Evans |
| D5050 | Julia Roberts |
| D3553 | Ann Pearson |

| PATIENT | |
|-----------------------|---------------|
| PK: Patient_number | Patient_name |
| P101 | Gil Ramirez |
| P108 | John Smith |
| P106 | Paul McCall |
| P110 | Andres Walker |

| SURGERY | |
|---------------------|-----------------|
| PK: Surgery_code | Surgery_name |
| S22 | Appendicitis |
| S10 | Cholecystectomy |
| S13 | Hip Replacement |

| APPOINTMENT | | | | |
|------------------------------|-------------------------------|-------------------------|-------------|---------------------|
| PK: Doctor_number (FK) | PK: Patient_number (FK) | PK: Appointment_Date | PK: Time | FK: Surgery_code |
| D1204 | P101 | 01-10-2025 | 10:00 | S22 |
| D1204 | P108 | 01-10-2025 | 12:00 | S22 |
| D5050 | P106 | 01-10-2025 | 10:00 | S10 |
| D5050 | P106 | 02-10-2025 | 14:00 | S10 |
| D3553 | P108 | 02-10-2025 | 10:00 | S22 |
| D3553 | P110 | 03-10-2025 | 18:00 | S13 |

2.7 Reflections

- All non-key attributes now depend on the full PK.
- Redundancy reduced.
- But still possible **transitive dependency** (e.g., Surgery_name depends on Surgery_code, which depends on Appointment).

STEP 3: Third Normal Form (3NF)

3.1 Rule (3NF)

- Must be in 2NF
- All non-key attributes must depend only on the primary key (no transitive dependency)

3.2 Issue

- Our design already separates dependencies — there are no transitive dependencies left. Each non-key column depends **only** on its table's PK.

3.3 Solution

The structure from 2NF already satisfies 3NF — this is the final normalized form.

3.4, 3.5, 3.6 same like step 2

3.7 Reflection

- All redundancy eliminated.

- No multi-valued or derived fields.
- All tables in 3NF.
- Primary and foreign keys defined correctly.
